

Big Data Processing and Analytics: Assignment 1

Louis MARTIN
louis.martin@student.ecp.fr

February 13, 2017

In this assignment we are going to create an inverted index on a corpus including the complete works of William Shakespear, Mark Twain and Jane Austen using Hadoop's MapReduce framework. The source code is available on Github.

1 Setup

(a) System specifications

- **Operating system:**
Ubuntu 16.04 (Native)
- **System specifications:**
Model: Dell Inspiron 17R 5720
Processor: i5-3210M
Cores: 2
Threads: 4
Ram: 8 GB
Storage: 256GB SSD (MLC)
- **Java version:**
openjdk version "1.8.0_121"
OpenJDK Runtime Environment (build 1.8.0_121-8u121-b13-0ubuntu1.16.04.2-b13)
OpenJDK 64-Bit Server VM (build 25.121-b13, mixed mode)
- **Hadoop version:**
Hadoop 2.7.3
Subversion <https://git-wip-us.apache.org/repos/asf/hadoop.git> -r baa91f7c6bc9cb92be5982de4719c1c8af91ccff
Compiled by root on 2016-08-18T01:41Z
Compiled with protoc 2.5.0
From source with checksum 2e4ce5f957ea4db193bce3734ff29ff4
This command was run using /usr/local/hadoop/share/hadoop/common/hadoop-common-2.7.3.jar

Hadoop was installed using this tutorial and configured using this tutorial.

(b) Configuration

The configuration comes from the official documentation for a single Hadoop node cluster. The following configuration files allows Hadoop and YARN to run in a pseudo-distributed mode.

- **core-site.xml:**

```
1 <configuration>
2     <property>
3         <name>fs.defaultFS</name>
4         <value>hdfs://localhost:9000</value>
```

```
5     </property>
6 </configuration>
```

- **hdfs-site.xml:**

```
1 <configuration>
2     <property>
3         <name>dfs.replication</name>
4         <value>1</value>
5     </property>
6 </configuration>
```

- **mapred-site.xml:**

```
1 <configuration>
2     <property>
3         <name>mapreduce.framework.name</name>
4         <value>yarn</value>
5     </property>
6 </configuration>
```

- **yarn-site.xml:**

```
1 <configuration>
2     <property>
3         <name>yarn.nodemanager.aux-services</name>
4         <value>mapreduce_shuffle</value>
5     </property>
6
7     <!--
8     To prevent unhealthy nodes and jobs hanging due to low disk space
9     http://stackoverflow.com/questions/29131449/why-does-hadoop-report-unhealthy-node-local-dirs-and-log-dirs-are-bad
10    -->
11     <property>
12         <name>yarn.nodemanager.disk-health-checker.max-disk-utilization-per-disk-percentage</name>
13         <value>98.5</value>
14     </property>
15 </configuration>
```

- **Commands to set up HDFS and YARN:**

```
1     # Format the filesystem
2     hdfs namenode -format
3     # Start HDFS
4     start-dfs.sh
5
6     # Create directories to execute MapReduce jobs
7     hdfs dfs -mkdir /user
8     hdfs dfs -mkdir /user/louis
9
10    # Put the data in HDFS
11    hdfs dfs -put ~/dev/bdpa/a1/data data
12
13    # Start YARN Ressource manager
14    start-yarn.sh
```

(c) Bugs encountered

I encountered a bug while running the MapReduce jobs where I would be logged out and all my processes would be killed with no warning. After investigation, I found that this is a known bug referenced here and caused by `/bin/kill` in ubuntu 16.04.

I compiled `procps-3.3.10` from source to solve the problem as indicated in launchpad but to no avail.

```

1  # (1) download the sourcecode
2  sudo apt-get source procps
3
4  # (2) install dependency
5  sudo apt-get build-dep procps
6
7  # (3) compile procps
8  cd procps-3.3.10
9  sudo dpkg-buildpackage

```

I tried another solution from this stackoverflow thread but it didn't work either. The supposed fix was to add

```

1  [login]
2  KillUserProcesses=no

```

to `/etc/systemd/logind.conf` and restart.

As I could find a solution I had to cope with the problem and restart all the services every once in a while.

2 Inverted index

Workflow

In order to facilitate compiling the `.java` files into `.jar` files, I created the `compile.sh` script which takes as input parameter the name of the main class of the `.java` file.

Example: `./compile.sh StopWords`.

compile.sh:

```

1  #!/bin/bash
2  rm -rf *.class *.jar;
3  hadoop com.sun.tools.javac.Main $1.java;
4  jar cf $1.jar $1*.class;

```

Assumptions

After investigating the results of the different mapreduce jobs, I chose to define all of the following characters as words separators in addition to space

Separators: `.,?!'()[]$*-;:|`

Even if I lost some hyphenated words and contractions like "first-born" or "He's", the gain in coherence and clarity was worth the hassle.

(a) Stop words

(30) Run a MapReduce program to identify stop words (words with frequency > 4000) for the given document corpus. Store them in a single csv file on HDFS (stopwords.csv). You can edit the several parts of the reducers' output after the job finishes (with `hdfs` commands or with a text editor), in order to merge them as a single csv file.

Based on the wordcount example from the official documentation, we implement a MapReduce program that retrieves all the stopwords from a corpus, i.e. it retrieves the words with wordcount greater than 4000.

The file is **StopWords.java**

- **Mapper:**

This mapper splits a string into words (tokens) and outputs one (key, value) pair for each word with the key being the word and the value equal to 1.

```

18  public static class TokenizerMapper
19      extends Mapper<Object, Text, Text, IntWritable>{
20
21      private final static IntWritable one = new IntWritable(1);
22      private Text word = new Text();
23
24      public void map(Object key, Text value, Context context
25                      ) throws IOException, InterruptedException {
26          // Splits a string to tokens (here words)
27          StringTokenizer itr = new StringTokenizer(value.toString(), "
28              .,?!\" '() [] $*-_ ;:|");
29          while (itr.hasMoreTokens()) {
30              word.set(itr.nextToken().toLowerCase().trim());
31              // Write one (key, value) pair to context
32              context.write(word, one);
33          }
34      }

```

- **Reducer:**

The reducers, simply counts the number of occurrences of each key writes it to the output file only if its count is greater than 4000.

```

36  public static class IntSumReducer
37      extends Reducer<Text, IntWritable, Text, IntWritable> {
38      private IntWritable result = new IntWritable(10);
39
40      public void reduce(Text key, Iterable<IntWritable> values,
41                        Context context
42                        ) throws IOException, InterruptedException {
43          int sum = 0;
44          for (IntWritable val : values) {
45              sum += val.get();
46          }
47          // Only write the key value pair if its frequency is high enough
48          if (sum > 4000){
49              result.set(sum);
50              context.write(key, result);
51          }
52      }
53  }

```

- **Job configuration:**

The MapReduce task is set to write the output as a csv file. We can set the number of reducers, combiner and compression through command line arguments.

```

55  public static void main(String[] args) throws Exception {
56      Configuration conf = new Configuration();
57      // Remove output folder if it exists
58      Path output = new Path(args[1]);
59      FileSystem hdfs = FileSystem.get(conf);
60      // delete existing directory
61      if (hdfs.exists(output)) {

```

```

62         hdfs.delete(output, true);
63     }
64
65     // Set separator to write as a csv file
66     conf.set("mapred.textoutputformat.separator", ", ");
67     // Set compression
68     if ((args.length >= 5) && (Integer.parseInt(args[4]) == 1)) {
69         conf.set("mapreduce.map.output.compress", "true");
70     }
71
72     Job job = Job.getInstance(conf, "stop words");
73     job.setJarByClass(StopWords.class);
74
75     // Set number of reducers and combiner through cli
76     if (args.length >= 3) {
77         job.setNumReduceTasks(Integer.parseInt(args[2]));
78     }
79     if ((args.length >= 4) && (Integer.parseInt(args[3]) == 1)) {
80         job.setCombinerClass(IntSumReducer.class);
81     }
82     job.setMapperClass(TokenizerMapper.class);
83     job.setReducerClass(IntSumReducer.class);
84
85     job.setOutputKeyClass(Text.class);
86     job.setOutputValueClass(IntWritable.class);
87     FileInputFormat.addInputPath(job, new Path(args[0]));
88     FileOutputFormat.setOutputPath(job, new Path(args[1]));
89     long startTime = System.nanoTime();
90     if (job.waitForCompletion(true)) {
91         long endTime = System.nanoTime();
92         float duration = (endTime - startTime);
93         duration /= 1000000000;
94         System.out.println("***** Elapsed: " + duration + "s *****\n");
95         System.exit(0);
96     }
97     else {
98         System.exit(1);
99     }
100 }
101 }

```

- **Script running the experiments:**

We run the set of experiments with the **run_stopwords.sh** script. This script executes the StopWords MapReduce task with different parameters and merges all the outputs into a csv file in HDFS.

```

1  #!/bin/bash
2  ./compile.sh StopWords
3
4  # Usage:
5  # hadoop jar myfile.jar Class input_dir output_dir n-reducers combiner
   compression
6
7  # 10 reducers no combiner
8  hadoop jar StopWords.jar StopWords data/corpus/ out 10 0 0;
9  hdfs dfs -getmerge out stopwords.csv;
10
11 # 10 reducers, combiner

```

```

12  hadoop jar StopWords.jar StopWords data/corpus/ out 10 1 0;
13  hdfs dfs -getmerge out stopwords.csv;
14
15  # 10 reducers, combiner, compression
16  hadoop jar StopWords.jar StopWords data/corpus/ out 10 1 1;
17  hdfs dfs -getmerge out stopwords.csv;
18
19  # 50 reducers, combiner, compression
20  hadoop jar StopWords.jar StopWords data/corpus/ out 50 1 1;
21  hdfs dfs -getmerge out stopwords.csv;

```

- **Results:** Here is an extract of the output csv:

```

10  with , 35591
11  good , 4632
12  from , 9677
13  has , 5190
14  its , 4569
15  man , 5267
16  made , 4046
17  not , 35143
18  said , 8434
19  have , 24625
20  my , 27231

```

- (10) Use 10 reducers and do not use a combiner. Report the execution time.

The running time with 10 reducers is **126 seconds**.

- (10) Run the same program again, this time using a Combiner. Report the execution time. Is there any difference in the execution time, compared to the previous execution? Why?

The running time with 10 reducers and combiner is **105 seconds**. The running time is lower with the combiner. Indeed the combiner takes the output of each mapper separately and tries to reduce as many (key, value) pairs coming from this specific mapper as it can. Combining the data like this will lower the load for the reducers, and all the intermediary steps between the mappers and the reducers such as network transfer (does not occur for a pseudo-distributed cluster), sorting all the (key, value) pairs, assigning them to each reducer...

- iii. (5) Run the same program again, this time compressing the intermediate results of map (using any codec you wish). Report the execution time. Is there any difference in the execution, time compared to the previous execution? Why?

Compression compresses the data between the mappers and the reducers. The running time with 10 reducers, combiner and compression is **125 seconds**. The running time increased. This can be explained by the fact that compression adds an additional overhead and its benefit is not used for a single node cluster! Indeed compression is often used to reduce network transfer times, which does not occur here as all the mappers and reducers are on the same device.

- iv. (5) Run the same program again, this time using 50 reducers. Report the execution time. Is there any difference in the execution time, compared to the previous execution? Why?

The running time with 50 reducers, combiner and compression is **126 seconds**. The running time is about the same as the previous experiment. We did not benefit from the additional number of reducers. This is logical because with a single node cluster, the processing power caps with the limited number of cores. No additional gain is achieved with this extra parallelization.

The screenshot shows the Hadoop Application Overview page for application `application_1486917381013_0001`. The page is divided into several sections:

- Cluster:** A sidebar menu with options like About, Nodes, Node Labels, Applications, NEW, NEW_SAVING, SUBMITTED, ACCEPTED, RUNNING, FINISHED, FAILED, KILLED, and Scheduler.
- Kill Application:** A section with a 'Kill Application' button.
- Application Overview:** A table showing application details:

- (b) (30) Implement a simple inverted index for the given document corpus, as shown in the previous Table, skipping the words of stopwords.csv.

The inverted index is implemented in `InvertedIndex.java`.

- **readStopWords function:**

First we need to read the stopwords from the csv file. We do it with the `readStopWords` function.

```

52 public static HashSet<String> readStopWords() {
53     // Read stopwords into a HashSet for fast membership testing
54     // The hashtable underlying structure provides O(1) membership testing
55     HashSet<String> stopWords = new HashSet<String>();
56
57     // Read csv file: inspired from https://www.mkyong.com/java/how-to-
58     // read-and-parse-csv-file-in-java/
59     String csvFile = "stopwords.csv";
60     BufferedReader br = null;
61     String line = "";
62     String cvsSplitBy = ",";
63
64     try {
65         br = new BufferedReader(new FileReader(csvFile));
66         while ((line = br.readLine()) != null) {
67             // use comma as separator
68             String[] splittedLine = line.split(cvsSplitBy);
69             stopWords.add(splittedLine[0]);
70         }
71     } catch (FileNotFoundException e) {
72         e.printStackTrace();
73     } catch (IOException e) {
74         e.printStackTrace();
75     } finally {
76         if (br != null) {
77             try {
78                 br.close();
79             } catch (IOException e) {
80                 e.printStackTrace();
81             }
82         }
83     }
84 }

```

```

82     }
83     return stopWords;
84 }

```

- **Mapper:**

Our mapper here outputs only words which are not in stopwords.csv as keys and the file from which they came from as values (formatted as a posting list). These posting lists are implemented using a custom class of MapWritable in order to have all the ComparableWritable properties that Hadoop's MapReduce needs (more details below). The posting list returned by the mapper is just a map containing one element which is a (key, value) pair of the form (filename, 1).

```

87     public static class TokenizerMapper
88         extends Mapper<Object, Text, Text, PostingListWritable>{
89         private Text word = new Text();
90         private Text doc = new Text();
91         private IntWritable one = new IntWritable(1);
92         private PostingListWritable postingList = new PostingListWritable();
93         private HashSet<String> stopWords = InvertedIndex.readStopWords();
94
95         public void map(Object key, Text value, Context context
96             ) throws IOException, InterruptedException {
97             FileSplit fileSplit = (FileSplit) context.getInputSplit();
98             String filename = fileSplit.getPath().getName();
99             doc.set(filename);
100
101             // Splits a string to tokens (here words)
102             StringTokenizer itr = new StringTokenizer(value.toString(), "
103                 .,?!\"'() []$*-_:;|");
104             String token = new String();
105             while (itr.hasMoreTokens()) {
106                 token = itr.nextToken().toLowerCase().trim();
107                 if (!stopWords.contains(token)) {
108                     word.set(token);
109                     // Output is a PostingListWritable containing the filename and the
110                     // value 1
111                     postingList.clear();
112                     postingList.put(doc, one);
113                     // Write one (key, value) pair to context
114                     context.write(word, postingList);
115                 }
116             }
117         }
118     }
119 }

```

- **Reducer:**

Our reducer reduces all the posting lists it receives and also counts the number of occurrences of each word for the following frequency part (more details below).

```

124     public void reduce(Text word, Iterable<PostingListWritable> postingLists
125         ,
126         Context context
127         ) throws IOException, InterruptedException {
128         // We are going to aggregate all posting lists together
129         postingList.clear();
130         // Iterate through all posting lists coming from the mappers or the
131         // combiners
132         for (PostingListWritable mw : postingLists) {

```

```

131      // Iterate through the entries of one given posting list
132      for (PostingListWritable.Entry<Writable, Writable> entry : mw.
          entrySet()) {
133          Text doc = (Text) entry.getKey();
134          IntWritable newValue = (IntWritable) entry.getValue();
135          if (postingList.containsKey(doc)) {
136              IntWritable oldValue = (IntWritable) postingList.get(doc);
137              postingList.put(doc, new IntWritable(oldValue.get() + newValue.
                  get()));
138          } else {
139              postingList.put(doc, new IntWritable(newValue.get()));
140          }
141      }
142  }
143
144      isLastWordInUniqueDoc = (postingList.size() == 1);
145      context.write(word, postingList);
146  }
147  }

```

- (c) (10) How many unique words exist in the document corpus (excluding stop words)? Which counter(s) reveal(s) this information? Define your own counter for the number of words appearing in a single document only. What is the value of this counter? Store the final value of this counter on a new file on HDFS.

The counter that counts the unique words in the documents is **TaskCounter.REDUCE_INPUT_GROUPS**. This counter counts the number of keys which is exactly the number of unique words.

In order to count the words appearing in a single document only, we implement the following counter:

```

31  public static enum WordCounter {
32      WORDS_IN_UNIQUE_DOC
33  };

```

Which is incremented in the reducer's reduce function:

```

160      if (isLastWordInUniqueDoc) {
161          // Increment counter for word appearing in a single document only
162          // We are guaranteed that this is the only time that the counter
163          // will be incremented for this word because all the values from
164          // a given key all go to the same reduce call.
165          context.getCounter(WordCounter.WORDS_IN_UNIQUE_DOC).increment(1);
166      }

```

The counter gives us a count **36343 words appearing in a single document only** which seems pretty high given the number of total unique words 56491 (excluding about 140 stopwords).

After investigation, a lot of words appear only in pg3200.txt which are the Mark Twain works. This file is roughly 300.000 lines long, which is about three times longer than the other files. This might explained why it contains a lot more vocabulary specific than the rest.

The counter value is stored in a file in HDFS:

```

220      // Write the count of unique words to a file in HDFS
221      Path filePath = new Path("words_in_unique_file.txt");
222      if (hdfs.exists(filePath)) {
223          hdfs.delete(filePath, true);
224      }
225      FSDataOutputStream fin = hdfs.create(filePath);
226      fin.writeUTF(message);

```

227 `fin.close();`

- (d) (30) Extend the inverted index of (b), in order to keep the frequency of each word for each document. You are required to use a Combiner.

- **PostingListWritable:**

As explained before we implemented a custom class extending MapWritable in order to have all the ComparableWritable properties that hadoop needs and to be able to use a combiner along with a reducer without losing the word frequencies during the transfer. The custom class allows pretty printing a MapWritable instance to a file.

```

36  public static class PostingListWritable extends MapWritable {
37      // Creates a custom class that overrides the toString method to pretty
38      // print the posting list
39      @Override
40      public String toString() {
41          String stringRepr = new String();
42          for (PostingListWritable.Entry<Writable, Writable> entry : this.
              entrySet()) {
43              stringRepr += entry.getKey() + "#" + entry.getValue() + ", ";
44          }
45          // Remove last comma and space of string
46          stringRepr = stringRepr.substring(0, stringRepr.length()-2);
47          return stringRepr;
48      }
49  }

```

- **Combiner:**

Different posting lists coming from different mappers or combiners can be reduced into a single one using the reduce function of the combiner.

```

119  public static class PostingListCombiner
120      extends Reducer<Text, PostingListWritable, Text, PostingListWritable>
121      {
122      private PostingListWritable postingList = new PostingListWritable();
123      protected boolean isLastWordInUniqueDoc = false;
124      public void reduce(Text word, Iterable<PostingListWritable> postingLists
125          ,
126                      Context context
127                      ) throws IOException, InterruptedException {
128          // We are going to aggregate all posting lists together
129          postingList.clear();
130          // Iterate through all posting lists coming from the mappers or the
131          // combiners
132          for (PostingListWritable mw : postingLists) {
133              // Iterate through the entries of one given posting list
134              for (PostingListWritable.Entry<Writable, Writable> entry : mw.
                  entrySet()) {
135                  Text doc = (Text) entry.getKey();
136                  IntWritable newValue = (IntWritable) entry.getValue();
137                  if (postingList.containsKey(doc)) {
138                      IntWritable oldValue = (IntWritable) postingList.get(doc);
139                      postingList.put(doc, new IntWritable(oldValue.get() + newValue.
                          get()));
140                  } else {
141                      postingList.put(doc, new IntWritable(newValue.get()));
142                  }
143              }
144          }
145      }
146  }

```

```

140     }
141   }
142 }
143
144     isLastWordInUniqueDoc = (postingList.size() == 1);
145     context.write(word, postingList);
146   }
147 }

```

- **Reducer:**

The reducer shares the reduce function (it is a child of the combiner) with the combiner with the only exception that it will increment the counter for words in unique documents (which should only occur once per key and therefore only in the reducer).

```

150   public static class PostingListReducer
151       extends PostingListCombiner {
152       // The only thing different between the reducer and the combiner is the
153       // counter incrementation. It must be incremented only once per key,
154       // hence in
155       // the reducer.
156       @Override
157       public void reduce(Text word, Iterable<PostingListWritable> postingLists
158           ,
159           Context context
160           ) throws IOException, InterruptedException {
161       super.reduce(word, postingLists, context);
162       if (isLastWordInUniqueDoc) {
163           // Increment counter for word appearing in a single document only
164           // We are guaranteed that this is the only time that the counter
165           // will be incremented for this word because all the values from
166           // a given key all go to the same reduce call.
167           context.getCounter(WordCounter.WORDS_IN_UNIQUE_DOC).increment(1);
168       }
169   }
170 }

```

- **Results:** Here is an extract of the output inverted index csv:

```

1741 enactment : pg3200.txt#2
1742 enchant : pg100.txt#4, pg3200.txt#2
1743 enchanting : pg31100.txt#1, pg100.txt#6, pg3200.txt#58

```

3 Conclusion

Inverted indexes are widely used for text retrieval or for search engines for the performance gain they provide. Creating an inverted index can however be a computing power intensive task but it can be highly parallelized. Hadoop's MapReduce framework is a perfect candidate for parallelizing this kind of task on a highly distributed cluster with no centralized data.
